Servo Tuning Ac The most common type of control loop, or algorithm, used for servo tuning is a PID loop, where "P" refers to proportional gain, "I" refers to integral gain, and "D" refers to derivative gain. A gain is essentially a ratio of output to input, and in a servo control loop, the gains determine how — and to what extent — the controller tries to correct the errors ...

Tuning a servo system involves adjusting the gains in the motion controller to minimize the servo system's response time, settling time, and overshoot. The goal of servo tuning is to minimize (but not necessarily eliminate) the error between the commanded position (or speed or torque) and the actual value achieved.

## **What is servo tuning and why is it important?**

Servo Tuning Servos are closed loop devices. They operate by comparing the position they're supposed to be at with the position their encoder says they actually are at and applying current to the servo motor until the two match.

## **CNCCookbook: Servo Tuning**

Servo tuning is the process by which tuning parameters are adjusted while the motor is installed within the machine for which it has been selected. The load must be coupled to the motor shaft and the move profile must be simulated as closely as possible to the actual operating conditions during the tuning process.

Scales introduce several variables into servo tuning. The motor encoder is used to control the velocity loop and the scale is used to control the positioning loop. There is always a lag between the motor encoder feedback and the scale feedback. That lag needs to be accounted for in the tuning.

## **Fanuc servo tuning - Practical Machinist**

Servo tuning has long relied on visual feedback to let engineers determine how well the motion parameters are working. Historically this was done with a standard electronic oscilloscope, but in the past ten years or more, motion analysis has typically occurred on a PC.

## **Tuning Servomotors [PDF] - Chudov**

Servo tuning can be achieved through a variety of procedures, but the most common method is to begin by increasing  $K_p$  until the system overshoots the target (the system is underdamped). Then  $K_d$  is increased until the system becomes critically damped (a balance between fast response and low overshoot).
